1. REMOVE ELEMENT

Given an integer array `nums` and an integer `val`, remove all occurrences of `val` in `nums` **inplace**. The relative order of the elements may be changed.

Since it is impossible to change the length of the array in some languages, you must instead have the result be placed in the first part of the `nums`. More formally, if there are `k` elements after removing the duplicates, then the first `k` elements of `nums` should hold the final result. It does not matter what you leave beyond `nums[k]`.

Return `k` after placing the final result in the first `k` slots of

Do not allocate extra space for another array. You must do this by modifying the input array **in-place** with $O(1)$ extra memory.

```
File Edit Format Run Options Window Help
def remove_element(nums, val):
    write_index = 0 # Initialize the write pointer

    for read_index in range(len(nums)):
        if nums[read_index] != val:
            nums[write_index] = nums[read_index]
            write_index += 1

    # The length of the array after removal is write_index
    return write_index

# Example usage
nums = [3, 2, 2, 3, 4, 2, 5]
val = 2
new_length = remove_element(nums, val)
print("New length:", new_length)
print("Modified array:", nums[:new_length])
```

OUTPUT:

```
das.py
New length: 4
```

Determine if a 9×9 Sudoku board is valid. Only the filled cells need to be validated

according to the following rules:

1. Each row must contain the digits 1-9 without repetition.
2. Each column must contain the digits 1-9 without repetition.
3. Each of the nine 3×3 sub-boxes of the grid must contain the digits 1-9 without repetition.

Note:

- A Sudoku board (partially filled) could be valid but is not necessarily solvable.
- Only the filled cells need to be validated according to the mentioned rules.

```

File Edit Format Run Options Window Help
def is_valid_sudoku(board):
    # Use sets to track the digits seen in rows, columns, and sub-boxes
    rows = [set() for _ in range(9)]
    columns = [set() for _ in range(9)]
    boxes = [set() for _ in range(9)]
    for i in range(9):

```

= RESTART: C:/Users/
312/sdas.py
True
>

```

37. Sudoku Solver

Write a program to solve a Sudoku puzzle by filling the empty cells.

A sudoku solution must satisfy all of the following rules:

1. Each of the digits

9

2. Each of the digits

1-

9

3. Each of the digits
of the grid.

1-

9

must occur exactly once in each of the 9 3x3

sub-boxes

The '.' character indicates empty cells.

1- must occur exactly once in each row.

File Edit Format Run Options Window Help

```
def solve_sudoku(board):
    def is_valid(board, row, col, num):
        # Check if 'num' is not in the current row, column, and 3x3 sub-box
        for i in range(9):
            if board[row][i] == num or board[i][col] == num:
                return False

        start_row, start_col = 3 * (row // 3), 3 * (col // 3)
        for i in range(start_row, start_row + 3):
            for j in range(start_col, start_col + 3):
                if board[i][j] == num:

3.Count and Say

The count-and-say sequence is a sequence of digit strings defined by the recursive formula:

- `countAndSay(1) = "1"`
- `countAndSay(n)` is the way you would "say" the digit string from `countAndSay(n1)`, which is then converted into a different digit string.

```
File Edit Format Run Options Window Help
def length_of_last_word(s):
    # Remove trailing spaces and split the string by spaces
    words = s.strip().split()

    # The last word is the last element in the list
    if words:
        return len(words[-1])
    else:
        return 0

# Example usage
s = "Hello World "
print(length_of_last_word(s)) # Output: 5
```

-
- **Output:**

```
= RESTART: C:/Users/  
312/sdas.py  
5
```

• To determine how you "say" a digit string, split it into the minimal number of substrings such that each substring contains exactly one unique digit. Then for each substring, say the number of digits, then say the digit. Finally, concatenate every said digit.

For example, the saying and conversion for digit string "3322251":

"3322251"

two 3's, three 2's, one 5, and one 1

2 3 + 3 2 + 1 5 + 1 1

"23321511"

File Edit Format Run Options Window Help

```
def count_and_say(n):
    if n == 1:
        return "1"

    previous = count_and_say(n - 1)
    result = []
    count = 1

    for i in range(1, len(previous)):
        if previous[i] == previous[i - 1]:
            count += 1
        else:
            result.append(str(count))
            result.append(previous[i - 1])
            count = 1

    result.append(str(count))
    result.append(previous[-1])

    return ''.join(result)

# Example usage
n = 5
print(count_and_say(n)) # Output: "111221"
```

OUTPUT:

```
= RESTART: C:/Users/go
312/sdas.py
111221
> |
```

39. Combination Sum

Given an array of distinct integers `candidates` and a target integer `target`, return *a list of all unique combinations of candidates where the chosen numbers sum to target*. You may return the combinations in any order.

The same number may be chosen from `candidates` an unlimited number of times. Two combinations are unique if the frequency of at least one of the chosen numbers is different. The test cases are generated such that the number of unique combinations that sum up to `target` is less than 150 combinations for the given input.

```
150
def combination_sum(candidates, target):
    def backtrack(remaining_target, combination, start_index):
        if remaining_target == 0:
            result.append(list(combination))
            return
        elif remaining_target < 0:
            return

        for i in range(start_index, len(candidates)):
            candidate = candidates[i]
            combination.append(candidate)
            backtrack(remaining_target - candidate, combination, i) # not i
            combination.pop()

    candidates.sort()
    result = []
    backtrack(target, [], 0)
    return result

# Example usage
candidates = [2, 3, 6, 7]
target = 7
print(combination_sum(candidates, target)) # Output: [[2, 2, 3], [7]]
```

OUTPUT:

```
= RESTART: C:/Users/gowtl
312/sdas.py
[[2, 2, 3], [7]]
>
```

40. Combination Sum II

Given a collection of candidate numbers (`candidates`) and a target number (`target`), find all unique combinations in `candidates` where the candidate numbers sum to `target`.

Each number in `candidates` may only be used once in the combination.

Note: The solution set must not contain duplicate combinations.

Example 1:

Input: `candidates = [10,1,2,7,6,1,5]`, `target = 8` Output:

```
[
  [1,1,6],
  [1,2,5],
  [1,7],
  [2,6]
]
```

Example 2:

Input: `candidates = [2,5,2,1,2]`, `target = 5` Output:

```
[
  [1,2,2],
  [5]
]
```

Constraints:

`1 <= candidates.length <= 100`

`1 <= candidates[i] <= 50`

- `1 <= target <= 30`

Permutations II

Given a collection of numbers, `nums`, that might contain duplicates, return *all possible unique permutations in any order*.

```
import itertools

def permute(nums):
    return list(itertools.permutations(nums))

# Example usage
n = 3
nums = list(range(1, n + 1))
print(permute(nums))
```

OUTPUT:

```
> = RESTART: C:/Users/gowth/AppData/Local/Programs/Python/Python
312/sdas.py
[(1, 2, 3), (1, 3, 2), (2, 1, 3), (2, 3, 1), (3, 1, 2), (3, 2,
1)]
> |
```

Length of Last Word

Given a string *s* consisting of words and spaces, return *the length of the last word in the string*.

A word is a maximal substring consisting of non-space characters only.

Permutation Sequence

The set $[1, 2, 3, \dots, n]$ contains a total of $n!$ unique permutations.

By listing and labeling all of the permutations in order, we get the following sequence for $n = 3$:

- 1.
2. "132"
3. "213"
- "231"
- "123"

4.

5. "312"

6. "321"

Given n and k , return the k th permutation sequence.

Example 1:

Input: $n = 3, k = 3$

Output: "213"

Example 2:

Input: $n = 4, k = 9$

Output: "2314"

Example 3:

Input: $n = 3, k = 1$

Output: "123"

Constraints:

$1 \leq n \leq 9$

• $1 \leq k \leq n!$
